Jupyter Exploration

Working through this lab, I established a clean, organized version control setup alongside an IDE. I started off by logging into my GitHub account and creating a new public repository named: **jupyter-exploration**. I wrote a brief summary describing the repository, I then launched Jupyter Notebook on my local machine (I already had it installed for my previous courses) via my PC's terminal. I typed in **jupyter notebook**, hit enter and my terminal ran the necessary codes to open Jupyter in my Microsoft Edge browser. Once in my dashboard, I created two new notebooks (**Jupyter-Exploration-ITAI2373.ipynb** and **Not_My_First_Notebook_ITAI1378.ipynb**), for each notebook I created a markdown cell and a code cell performing a `print("")` function as the assignment asked. After completing each notebook, I then downloaded each **.ipynb** file to my local drive and uploaded them via GitHub to my **jupyter-exploration** repository I created for this assignment.

Going through this lab was a great refresher on linking a local setup with GitHub. Since I have already worked with Jupyter before in my previous courses, the interface was not new to me. It was a simple process of getting my repository set up, making sure my notebooks were formatted with the right Markdown and code cells, and testing the Python print statements to confirm everything ran properly. Creating the repository on GitHub gives me an easy place to store and organize my work online instead of just keeping files on my local drive. I didn't run into any issues during the lab since the terminal commands and notebook setup worked as needed. Having established this setup early makes managing future assignments a lot easier. As

the semester progresses and the labs get into more complex programming tasks, data handling, or building out actual models, I already have a central repository connected to my account where everything can be pushed and updated directly. It keeps all my coursework in one spot and ensures that if I ever switch machines or need to access a project from somewhere else, the files and commit history are completely backed up and available on GitHub without needing to reconfigure the local workspace from scratch.
